

The Binary Tree Remove Algorithm

```
public void remove(Comparable val) {  
    root = remove(val, root);  
}  
  
private TreeNode remove(Comparable val, TreeNode tree) {  
    if there's no node  
        return null  
  
    if val < current value  
        set tree's left child to be the result of a call to the remove method on the left subtree  
    otherwise if val > current value  
        set tree's right child to be the result of a call to the remove method on the right subtree  
    otherwise:  
        If tree has no right child:  
            set tree to be tree's left child (which might set tree to null)  
        otherwise:  
            find the successor value (the smallest value in the right subtree).  
            set tree's value to that of the successor value.  
            remove the successor from the right subtree and make the result the new right child  
    return tree  
}
```
